FOREWORD

We would like to express our thanks to Mr. Glynn Woods, GCS Consulting Services., Mr. Willy Lock and Dr. Delin Wang of PRG (Paulin Research Group), Dr. Hans Bos of Dynaflow Research Group bv., Mr. Ron Haupt of Pressure Piping Engineering Associates, Inc., Mr. Randy Bethea, Tim Pline, and Russ Diedrich of Huntington Ingalls Industries – Newport News Shipbuilding, and Mr. Doug Knode and Edwin Avila of Evident Scientific/Olympus. Their assistance, comments and recommendations are very much appreciated.

Established in 1880, the ASME is a professional not-for-profit organization with more than 125,000 members and volunteers promoting the art, science and practice of mechanical and multidisciplinary engineering and allied sciences. ASME develops codes and standards that enhance public safety, and provides lifelong learning and technical exchange opportunities benefiting the engineering and technology community. Visit <https://www.asme.org/> for more information.

ASME ST-LLC is a not-for-profit Limited Liability Company, with ASME as the sole member, formed in 2004 to carry out work related to new and developing technology. ASME ST-LLC's mission includes meeting the needs of industry and government by providing new standards-related products and services, which advance the application of emerging and newly commercialized science and technology, and providing the research and technology development needed to establish and maintain the technical relevance of codes and standards. Visit <http://asmestllc.org/> for more information.

ABSTRACT

In support of ASME B31J and B31H standards, physical testing for stress intensification factors (SIFs), flexibility factors (k-Factors), and sustained stress indices (SSIs) can be used to confirm differences between the Markl and Hinnant curves in the low-cycle ranges and finite element predictions of fatigue, stiffness, collapse and burst.

Improvement in analytical capability since the 1950s (when Markl developed the basic rules in the B31 piping codes used today) has improved the ability to numerically predict stress states. Unfortunately, not all piping components are well defined geometrically or dimensionally in ASME standard documents. Large D/T (ratio of mean header diameter to header nominal thickness) and d/D (ratio of mean branch diameter to mean header diameter) failures involve nonlinear characteristics that may not be well represented by elastic analyses. In these cases, verification by test is considered essential to verify the predicted values and the method of analysis considered.

This publication documents the results of phase II of work undertaken to investigate deficiencies in the existing test data sets identified during the data collection effort from ST-LLC Publication STP-PT-073.

1 INTRODUCTION

Twelve straight pipe specimens were fabricated, material properties independently evaluated, and each specimen was pressurized to rupture at K&H Fabricator's facility in Smithville, Texas. The specimens were segregated into stainless and carbon groups, each group consisting of six specimens: three seamless specimens and three longitudinally welded specimens. Pipe specimens for each group of three tests were made from the same heat so that theoretically three identical specimens could be tested. A significant finding of these results is stainless steel samples failed at a consistently lower pressure than would otherwise be predicted for the same specimen made of carbon steel. This supports prior findings by Rodabaugh in [1].
